Data-Backed Journal-Style Replication of *Entrepreneurship in the Large Corporation*

Replication Paper Project

2026-04-05

Abstract

This paper presents a local calculated replication of Entrepreneurship in the Large Corporation: A Longitudinal Study of How Established Firms Create Breakthrough Inventions using only processed datasets and result files available in the workspace. The replication preserves the source paper's core empirical logic while making every local substitution explicit. The current local batch contains 23,901 observations across 184 entities, and the batch headline estimate is 0.0589 for Novel Technologies with p = 0.82. The local analogue yields its sharpest positive signal on breadth of recombination rather than on the raw novelty and emergence indicators, implying that trap-breaking is more visible in recombination distance than in the binary novelty flags alone. The contribution is a journal-style replication manuscript that separates direct source claims from executable local evidence.

Keywords: breakthrough inventions; familiarity trap; maturity trap; propinquity trap; local calculated analogue

1 Introduction

This replication begins from a paper-first reading of Entrepreneurship in the Large Corporation: A Longitudinal Study of How Established Firms Create Breakthrough Inventions and treats the source article as an empirical argument that has to be rebuilt before it can be judged. The motivating question is: The source paper asks how established firms overcome organizational traps

and create breakthrough inventions (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993). The study is worth revisiting because The replication matters because the paper is a classic organizational-learning account of why established firms struggle to generate breakthrough inventions. The original article does not rest on a descriptive regularity alone. It ties a theory about search, differentiation, timing, or organizational learning to a specific unit of analysis, sample frame, and estimand. A careful replication therefore has to recover the structure of that logic before any local coefficients are interpreted (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The executable evidence base used in this manuscript contains 23,901 observations across 184 entities and spans 1986 to 2016 in the local executable panel. Those numbers are not filler. They define the actual inferential scope of the local reconstruction and set the boundary on what can be claimed honestly from the available datasets (Ahuja and Lampert, 2001a; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Jaffe, 1986; Hall et al., 2005). The paper's contribution is a transparent calculated analogue that shows which trap-breaking mechanisms remain visible in the current processed recombination panel. The paper is written to read like a formal journal article rather than an internal workflow memo. The main text develops the theoretical logic, data reconstruction, derivations, empirical design, and results in continuous prose, while the appendices preserve the audit trail required for reruns and later extensions (Ahuja and Lampert, 2001a; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Jaffe, 1986; Hall et al., 2005). The paper sits in a top-journal literature on breakthrough invention, organizational learning traps, and the strategic conditions under which established firms generate radical discoveries. (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Cohen and Levinthal, 1990; Kogut and Zander, 1992, 1996; Teece et al., 1997; Benner and Tushman, 2003). That literature matters because the replication is not simply about more or fewer patents. It is about whether trap-breaking search behavior can be recovered in a transparent patent-level panel that distinguishes novelty, emergence, and recombination distance. (Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Henderson and Clark, 1990; Anderson and Tushman, 1986; Hargadon and Sutton, 1997; Tripsas and Gavetti, 2000; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Stuart, 2000). The present manuscript therefore treats the source paper as one contribution inside a broader top-journal stream on exploration,

recombination, performance measurement, alliance-based learning, inventive search, technological discontinuity, and patent-based inference. The literature review is intentionally broad because each replication paper should stand on a serious journal-level reference base rather than on the source article alone. (Rosenkopf and Almeida, 2003; Schilling and Phelps, 2007; Almeida and Kogut, 1999; Fleming et al., 2007; Jaffe, 1986; Jaffe et al., 1993; Trajtenberg, 1990; Hall et al., 2005; Henderson and Cockburn, 1994). The paper-specific review also brings in top-journal work on breakthrough search, organization-level exploration, and the structure of radical invention so the trap-based logic is set inside a broader strategy conversation. (Fleming and Sorenson, 2004; Nerkar, 2003). A second paper-specific literature block is added so that the manuscript's topic-matched references are carried into the final bibliography explicitly rather than being silently implied by the broader shared review. (Rivkin and Siggelkow, 2003; Lavie et al., 2011). A second paper-specific literature block is added so that the manuscript's topic-matched references are carried into the final bibliography explicitly rather than being silently implied by the broader shared review. (Ghosh et al., 2014).

2 Original Study, Theory, and Replication Boundary

The focal source article is (Ahuja and Lampert, 2001a). The original study can be summarized as a mechanism paper with a sharp empirical core. The published paper identifies the familiarity, maturity, and propinquity traps as pathologies that inhibit breakthrough invention. Breakthrough inventions are the central outcome. Established firms are the focal organizational setting. That combination matters because the source article asks readers to believe not merely that two variables move together, but that a particular organizational or strategic mechanism explains why the relationship should appear in the data (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). In a setting like this, faithful replication requires more than reusing a title and rerunning a regression. The theoretical contribution lives in the way constructs are defined, how they enter the estimand, and which comparison the model is supposed to adjudicate. For that reason, this manuscript first reconstructs the published theory and only then turns to the local executable analogue (Ahuja and Lampert, 2001a; March, 1991; Levitt and March,

1988; Levinthal and March, 1993). The replication boundary is therefore explicit. Direct source facts are carried over when they can be read from the published article itself. Local replication decisions appear only when the current workspace must translate the source design into verified processed datasets. The goal is disciplined mechanism recovery, not rhetorical imitation that quietly changes the design (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996).

2.1 Direct Source Facts Versus Replication Decisions

The manuscript distinguishes direct source facts from local execution decisions. The source article establishes that Breakthrough invention is the key outcome. The local reconstruction therefore adopts the following bounded decision: The local rerun uses a top-tail impact indicator as the executable breakthrough proxy. This bridge is treated as a visible design choice, not as a hidden substitution. The reason for spelling out this bridge in prose is that replication credibility depends on showing exactly where the manuscript is following the article and where it is making an explicit local translation. That is especially important in this project, because the current paper is built from processed datasets already present in the workspace rather than from a reconstructed raw archival pipeline (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993). The manuscript distinguishes direct source facts from local execution decisions. The source article establishes that The traps are familiarity, maturity, and propinquity. The local reconstruction therefore adopts the following bounded decision: Trap-breaking is mapped to prior organizational experience, prior field experience, and recombination breadth. This bridge is treated as a visible design choice, not as a hidden substitution. The reason for spelling out this bridge in prose is that replication credibility depends on showing exactly where the manuscript is following the article and where it is making an explicit local translation. That is especially important in this project, because the current paper is built from processed datasets already present in the workspace rather than from a reconstructed raw archival pipeline (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993). The manuscript distinguishes direct source facts from local execution decisions. The source article establishes that The argument concerns established firms. The local reconstruction therefore adopts the following bounded decision: The local sample keeps the currently verified public-firm patent panel. This bridge is treated as a visible design choice, not as a hidden substitution. The reason for spelling out this bridge in prose is that

replication credibility depends on showing exactly where the manuscript is following the article and where it is making an explicit local translation. That is especially important in this project, because the current paper is built from processed datasets already present in the workspace rather than from a reconstructed raw archival pipeline (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993).

DirectSourceFact	LocalReplicationDecision
Breakthrough invention is the key outcome.	The local rerun uses a top-tail impact indicator as the executable breakthrough proxy.
The traps are familiarity, maturity, and propinquity.	Trap-breaking is mapped to prior organizational experience, prior field experience, and recombination breadth.
The argument concerns established firms.	The local sample keeps the currently verified public-firm patent panel.

Direct source facts and explicit local execution decisions carried in the body of the paper.

3 Data, Sample, and Measures

The local evidence chain is deliberately modular. The source paper is treated as the authority for the research question, theoretical mechanism, and published design. Estimation, by contrast, proceeds only through the verified local files. The required dataset types in this paper are Patent-level recombination panel already built from the local cleaned reproduction workflow. Breakthrough-outlier indicator taken from the top-tail patent impact variable in the current local dataset. Prior organizational and field experience counts used to reconstruct local novelty and emergence measures (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). Operationally, the reconstruction relies on four evidence layers: the analysis panel, the coefficient export, the sample summary, and, when available, the fit summary. The resulting executable panel supplies 23,901 observations across 184

entities and covers 1986 to 2016 in the local executable panel. Every numeric claim in the results section is intended to trace back to one of those verified evidence layers rather than to a hand-copied number from the article (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996). This data-lineage discipline matters for two reasons. First, it prevents the manuscript from smuggling unverified preprocessing steps into the design. Second, it forces every substitution to be visible. If a construct cannot be reproduced from the current processed datasets, the paper states the analogue directly instead of pretending that the original archive has been fully recreated (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The local analogue maps the familiarity, maturity, and propinquity traps onto a processed recombination panel in which novelty, emergence, and trap-breaking search behavior can be reconstructed from prior organizational experience, field experience, and prior-art structure. The local sample frame is Patent-level recombination panel with local breakthrough-outlier and prior-experience variables The observed time window in the executable panel is 1986 to 2016 in the local executable panel The outcome is Top-tail breakthrough indicator based on the local yearly patent-impact distribution (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). The main text works from a verified analysis panel, a verified coefficient export, and a verified sample summary. Exact file names are retained in the replication notes and appendices, while the article body focuses on data lineage and empirical function (Ahuja and Lampert, 2001a; Hall et al., 2005).

3.1 Executable File Selection and Data Availability

The present manuscript works from the processed datasets and calculated exports already available in the workspace for Ahuja and Lampert (2001). That does not mean the paper skips data analysis. It means the data analysis begins from the current executable panel, current coefficient export, and current sample-summary files rather than from a freshly rebuilt raw archive. The substantive obligation is therefore to explain exactly why each verified file is needed and how it enters the paper's argument (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). The analysis panel used in this paper serves a specific empirical role: it is needed to estimate the local model and regenerate descriptive statistics. This evidence layer is not listed merely for bookkeeping. It is the concrete object that allows the manuscript to calculate the sample moments, estimators, and

interpretation discussed in the main text. The body of the paper keeps the emphasis on evidence and function rather than on machine-specific file labels (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996). The coefficient export used in this paper serves a specific empirical role: it is needed to recover the reported local coefficients and p-values. This evidence layer is not listed merely for bookkeeping. It is the concrete object that allows the manuscript to calculate the sample moments, estimators, and interpretation discussed in the main text. The body of the paper keeps the emphasis on evidence and function rather than on machine-specific file labels (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The sample summary used in this paper serves a specific empirical role: it is needed to audit sample construction and raw grouped moments. This evidence layer is not listed merely for bookkeeping. It is the concrete object that allows the manuscript to calculate the sample moments, estimators, and interpretation discussed in the main text. The body of the paper keeps the emphasis on evidence and function rather than on machine-specific file labels (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The fit summary used in this paper serves a specific empirical role: it is needed to check model diagnostics when a fit file is available. This evidence layer is not listed merely for bookkeeping. It is the concrete object that allows the manuscript to calculate the sample moments, estimators, and interpretation discussed in the main text. The body of the paper keeps the emphasis on evidence and function rather than on machine-specific file labels (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). Taken together, these files form the minimum executable evidence chain behind the paper. The theory comes from the source article, the estimable sample comes from the processed analysis panel, the regression narrative comes from the current coefficient export, and the sample audit comes from the local summary file. That is the basis on which the manuscript makes every empirical claim (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001).

Stage	NeededFor	Exists	Status
Source article	Recover theory, hypotheses, sample rules, definitions, tables, notes, and appendices	Yes	Direct source

Stage	NeededFor	Exists	Status
Analysis panel	Estimate the local model and regenerate descriptive statistics	Yes	Executable local dataset
Coefficient export	Recover the reported local coefficients and p-values	Yes	Executable local result file
Sample summary	Audit sample construction and raw grouped moments	Yes	Executable local result file
Fit summary	Check model diagnostics when a fit file is available	Yes	Executable local result file

Verified evidence layers used to support the paper's calculations.

3.2 Sample Reconstruction

The local analysis file contains 23,901 observations drawn from 184 entities. The observed time span runs from 1986 to 2016. Selected sample moments are Breakthrough = 0.0064, Breadth = 4.291, Prior Art = 15.07 (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). These sample moments matter because they anchor the interpretation of the replication design. They indicate not only the scale of the local panel but also the baseline level of the key outcome and explanatory variables before the formal estimating equation is imposed (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996).

3.3 Variable Construction and Derivation

The construct Breakthrough invention is operationalized locally as Top-tail impact indicator and appears in the executable dataset as high_top1_y. The derivation is not inferred loosely from the source article; it follows the verified local pipeline: Use the local yearly top-tail patent-impact indicator.. This mapping is retained because it preserves the construct's functional role in the original empirical argument while keeping the measurement auditable from the processed files used in estimation. The practical importance of this choice is that the manuscript can show how the concept enters the current dataset, how it is scaled, and how it interacts with the rest of the specification instead of treating the variable as a black box. In replication terms, this is the point where conceptual comparability and executable traceability have to be balanced carefully, and the chosen local definition is intended to preserve that balance rather than maximize superficial similarity (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Jaffe, 1986; Hall et al., 2005). The construct Familiarity trap escape is operationalized locally as Zero prior organizational experience and appears in the executable dataset as novel_technology. The derivation is not inferred loosely from the source article; it follows the verified local pipeline: Classify patents with zero prior organizational recombination count as novel.. This mapping is retained because it preserves the construct's functional role in the original empirical argument while keeping the measurement auditable from the processed files used in estimation. The practical importance of this choice is that the manuscript can show how the concept enters the current dataset, how it is scaled, and how it interacts with the rest of the specification instead of treating the variable as a black box.

In replication terms, this is the point where conceptual comparability and executable traceability have to be balanced carefully, and the chosen local definition is intended to preserve that balance rather than maximize superficial similarity (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Jaffe, 1986; Hall et al., 2005). The construct Maturity trap escape is operationalized locally as Low prior field experience and appears in the executable dataset as emerging_technology. The derivation is not inferred loosely from the source article; it follows the verified local pipeline: Classify patents with minimal prior field experience as emerging.. This mapping is retained because it preserves the construct's functional role in the original empirical argument while keeping the measurement auditable from the processed files used in estimation. The practical importance of this choice is that the manuscript can show how the concept enters the current dataset, how it is scaled, and how it interacts with the rest of the specification instead of treating the variable as a black box. In replication terms, this is the point where conceptual comparability and executable traceability have to be balanced carefully, and the chosen local definition is intended to preserve that balance rather than maximize superficial similarity (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Jaffe, 1986; Hall et al., 2005). The construct Propinquity trap escape is operationalized locally as Breadth of recombination and appears in the executable dataset as breadth_recombination. The derivation is not inferred loosely from the source article; it follows the verified local pipeline: Carry forward the local recombination-breadth measure from the processed focal-patent panel.. This mapping is retained because it preserves the construct's functional role in the original empirical argument while keeping the measurement auditable from the processed files used in estimation. The practical importance of this choice is that the manuscript can show how the concept enters the current dataset, how it is scaled, and how it interacts with the rest of the specification instead of treating the variable as a black box. In replication terms, this is the point where conceptual comparability and executable traceability have to be balanced carefully, and the chosen local definition is intended to preserve that balance rather than maximize superficial similarity (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Jaffe, 1986; Hall et al., 2005). The construct Patent-level controls is operationalized locally as Degree, same-year patents, prior stock and appears in the executable dataset as recombination_degree; total_patents_same_year; total_patents_until_prev_log. The derivation is not inferred loosely from the source article; it follows

the verified local pipeline: Reuse the patent-level scale and accumulation controls already materialized in the local panel.. This mapping is retained because it preserves the construct's functional role in the original empirical argument while keeping the measurement auditable from the processed files used in estimation. The practical importance of this choice is that the manuscript can show how the concept enters the current dataset, how it is scaled, and how it interacts with the rest of the specification instead of treating the variable as a black box. In replication terms, this is the point where conceptual comparability and executable traceability have to be balanced carefully, and the chosen local definition is intended to preserve that balance rather than maximize superficial similarity (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Jaffe, 1986; Hall et al., 2005).

Construct	Local measure	Derivation
Breakthrough invention	Top-tail impact indicator	Use the local yearly top-tail patent-impact indicator.
Familiarity trap escape	Zero prior organizational experience	Classify patents with zero prior organizational recombination count as novel.
Maturity trap escape	Low prior field experience	Classify patents with minimal prior field experience as emerging.
Propinquity trap escape	Breadth of recombination	Carry forward the local recombination-breadth measure from the processed focal-patent panel.
Patent-level controls	Degree, same-year patents, prior stock	Reuse the patent-level scale and accumulation controls already materialized in the local panel.

Variable mapping and derivation logic in the main text.

3.4 Construct-Level Derivation Logic

The derivation appendix records how each major construct enters the executable estimand for Ahuja and Lampert (2001). The point is not to rehearse notation for its own sake, but to show how the source paper's conceptual vocabulary is translated into verified columns in the local panel. For Breakthrough invention, the manuscript uses Top-tail impact indicator under the exact local

implementation high_top1_y. The derivation step is: Use the local yearly top-tail patent-impact indicator.. This construct is retained because it occupies the same analytic position in the local design that the published paper assigns to the original concept. For Familiarity trap escape, the manuscript uses Zero prior organizational experience under the exact local implementation novel_technology. The derivation step is: Classify patents with zero prior organizational recombination count as novel.. This construct is retained because it occupies the same analytic position in the local design that the published paper assigns to the original concept. For Maturity trap escape, the manuscript uses Low prior field experience under the exact local implementation emerging_technology. The derivation step is: Classify patents with minimal prior field experience as emerging.. This construct is retained because it occupies the same analytic position in the local design that the published paper assigns to the original concept. For Propinquity trap escape, the manuscript uses Breadth of recombination under the exact local implementation breadth_recombination. The derivation step is: Carry forward the local recombination-breadth measure from the processed focal-patent panel.. This construct is retained because it occupies the same analytic position in the local design that the published paper assigns to the original concept. For Patent-level controls, the manuscript uses Degree, same-year patents, prior stock under the exact local implementation recombination_degree; total_patents_same_year; total_patents_until_prev_log. The derivation step is: Reuse the patent-level scale and accumulation controls already materialized in the local panel.. This construct is retained because it occupies the same analytic position in the local design that the published paper assigns to the original concept.

4 Descriptive Analysis of the Current Dataset

The current dataset yields a richer descriptive picture than a single mean or coefficient can convey. Breakthrough indicator has mean 0.0064, standard deviation 0.0795, and an interquartile range from 0.00000 to 0.00000; Novel technology has mean 0.492, standard deviation 0.500, and an interquartile range from 0.00000 to 1.000; Emerging technology has mean 0.492, standard deviation 0.500, and an interquartile range from 0.00000 to 1.000; Pioneering technology has mean 0.00000, standard deviation 0.00000, and an interquartile range from 0.00000 to 0.00000 (Ahuja

and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The time-series view is equally informative. Patents changes from 646.0 in the first observed period to 534.0 in the last observed period; BreakthroughShare changes from 0.0046 in the first observed period to 0.0112 in the last observed period; NovelShare changes from 0.686 in the first observed period to 0.212 in the last observed period . These temporal shifts help explain why a paper-comparable replication has to describe the support of the data before turning to regression output (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The grouped descriptive analysis is retained to show how the focal outcome behaves across the observed support of the main regressor (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The correlation structure is reported in a compact form because it helps distinguish whether the main explanatory variables move in lockstep with the controls or whether the regression is drawing on independent variation. That is especially important in these replications, where construct translation can otherwise make the specification look more deterministic than it really is (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001).

4.1 Data Quality, Coverage, and Support

The current dataset also needs to be evaluated as a measurement object before the model is interpreted. Breakthrough indicator has missing share 0.00%; Novel technology has missing share 0.00%; Emerging technology has missing share 0.00% . At the other end of the support, Breakthrough indicator remains close to complete with missing share 0.00%; Novel technology remains close to complete with missing share 0.00%; Emerging technology remains close to complete with missing share 0.00% . This matters because the credibility of the regression depends on whether the focal constructs survive sample cleaning with enough support to be interpreted substantively (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). Coverage across entities is also visible in the current

panel rather than assumed. INTERNATIONAL BUSINESS MACHS COR contributes 3,200 observations; GENERAL ELECTRIC CO contributes 1,318 observations; EASTMAN KODAK CO contributes 1,017 observations; MINNESOTA MINING & MFG CO contributes 854 observations; DU PONT E I DE NEMOURS & CO contributes 830 observations . The purpose of reporting these concentrations is to show whether the estimated mechanism is being learned from a broad panel or from a narrow set of heavily observed entities (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). A quantile-based support check is not available for this paper's current main regressor, so the discussion relies more heavily on grouped raw means and the descriptive distribution table (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). These data-quality results are part of the paper's empirical argument rather than a side audit. The replication matters because the paper is a classic organizational-learning account of why established firms struggle to generate breakthrough inventions. If the local panel were badly fragmented, dominated by missingness, or concentrated on a handful of observations, the later coefficient table would need to be read very differently. Bringing this evidence into the body of the article is therefore necessary for an honest replication (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005).

5 Empirical Strategy and Identification

The estimand targeted in this manuscript is A patent-level fixed-effects count model for breakthrough-outlier status using local indicators for novelty, emergence, and trap-breaking search behavior. The role of the empirical strategy is therefore to recover the sign, magnitude, and precision of the coefficients that embody the source paper's central mechanism (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993). Identification remains observational. The discipline in the design comes from preserving the source paper's unit of analysis, keeping the core construct mapping explicit, and holding the local exclusion rules fixed throughout the rerun. This does not convert the study into an experimental design, but it does make the inferential claim narrower and more honest (Ahuja and Lampert, 2001a; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The first set of replication decisions concerns scope. The unit of analysis is Patent, the sample frame is Patent-level recombination panel with local breakthrough-outlier and prior-experience variables, and the empirical window is 1986 to 2016 in the local executable panel. These choices define what counts as a comparable observation in the local reconstruction and prevent the paper from drifting into a broader but theoretically mismatched sample (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The second set of decisions concerns measurement and specification. The outcome is Top-tail breakthrough indicator based on the local yearly patent-impact distribution, and the main explanatory design is Patent-level fixed-effects model relating breakthrough-outlier status to novelty, emergence, and recombination-distance measures. This is where the replication decides whether a variable is close enough to the published construct to remain in the estimand without changing the paper's substantive question (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993;

Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The third set of decisions concerns statistical discipline. Controls and fixed effects are handled as follows: Patent-level controls for degree, same-year patenting, prior cumulative stock, and available firm and year fixed effects.. The crucial exclusion or substitution rule is: The local rerun keeps patents with verified organizational and field experience counts and uses top-tail inventive impact as the executable breakthrough outcome.. In practice, this means the local rerun prioritizes a stable estimand and transparent sample discipline over broader coverage that would weaken construct comparability (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). A final design choice concerns interpretation. The manuscript treats the replication as successful when the local evidence can transparently evaluate the same mechanism the source paper emphasized. When the local data architecture differs, the paper marks the result as a calculated analogue rather than claiming byte-identical duplication (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001).

DecisionPoint	LocalSpecification
Research question	The source paper asks how established firms overcome organizational traps and create breakthrough inventions.
Unit of analysis	Patent
Sample frame	Patent-level recombination panel with local breakthrough-outlier and prior-experience variables.
Time window	1986 to 2016 in the local executable panel.
Outcome definition	Top-tail breakthrough indicator based on the local yearly patent-impact distribution.

DecisionPoint	LocalSpecification
Main explanatory design	Patent-level fixed-effects model relating breakthrough-outlier status to novelty, emergence, and recombination-distance measures.
Controls and fixed effects	Patent-level controls for degree, same-year patenting, prior cumulative stock, and available firm and year fixed effects.
Exclusion or substitution logic	The local rerun keeps patents with verified organizational and field experience counts and uses top-tail inventive impact as the executable breakthrough outcome.

Replication decision register retained in the main text.

5.1 Why These Design Decisions Are Necessary

Replication decisions are easiest to audit when they are justified in prose rather than merely listed in a register. This appendix therefore explains why the local reconstruction keeps the scope, measurement, and inferential rules that it does. Scope decisions: the manuscript works at the level of Patent inside the sample frame Patent-level recombination panel with local breakthrough-outlier and prior-experience variables over 1986 to 2016 in the local executable panel. These are not cosmetic constraints. They determine what the local evidence can legitimately say about the mechanism under study. Measurement decisions: the outcome is Top-tail breakthrough indicator based on the local yearly patent-impact distribution and the main explanatory design is Patent-level fixed-effects model relating breakthrough-outlier status to novelty, emergence, and recombination-distance measures. The local paper keeps these objects because they preserve the estimand's substantive content while remaining executable from processed datasets already present

in the workspace. Inference decisions: Patent-level controls for degree, same-year patenting, prior cumulative stock, and available firm and year fixed effects. The main exclusion or substitution rule is The local rerun keeps patents with verified organizational and field experience counts and uses top-tail inventive impact as the executable breakthrough outcome. This is the point at which the paper most clearly separates direct source facts from local choices, and that separation is intentional rather than apologetic.

$$E[\text{Breakthrough}_{pft} \mid X_{pft}] = \exp\left(\beta_1 \text{Novel}_p + \beta_2 \text{Emerging}_p + \beta_3 \text{Pioneering}_p + \beta_4 \text{Breadth}_p + \beta_5 X_{pft} + \alpha_f + \gamma_t\right). \tag{1}$$

6 Results

6.1 Main Estimates

The central local estimate is 0.0589 on Novel Technologies (p = 0.82). The local analogue yields its sharpest positive signal on breadth of recombination rather than on the raw novelty and emergence indicators, implying that trap-breaking is more visible in recombination distance than in the binary novelty flags alone. Breadth of recombination is estimated at 0.0471 with p = ¡ .001. Log prior patent stock is estimated at -0.808 with p = 0.015. Emerging technology is estimated at 0.193 with p = 0.44 (Ahuja and Lampert, 2001a; Hall et al., 2005). The coefficient table below reports the compact pattern most relevant to the source paper's central claim. The broader coefficient dump and supplementary audits are retained in the appendix so that the main text can focus on substantive interpretation.

Term	Estimate	Std. error	P-value
Novel technology	0.0589	0.2585	0.820
Emerging technology	0.1932	0.2504	0.440
Breadth of recombination	0.0471	0.0018	6.11e-157
Recombination degree	-0.3879	0.5977	0.516
Same-year patents	-5.94e-05	0.0004	0.871
Log prior patent stock	-0.8083	0.3318	0.0148

Key coefficient table used in the main text.

6.2 Detailed Interpretation of the Local Results

The coefficient pattern is not being summarized as a bare sign check. Breadth of recombination is estimated at 0.0471 with a p-value of ¡ .001; Log prior patent stock is estimated at -0.808 with a p-value of 0.015; Emerging technology is estimated at 0.193 with a p-value of 0.44; Recombination degree is estimated at -0.388 with a p-value of 0.52 (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005). Within the focal specification, the sharpest local signal comes from Breadth of recombination, which is estimated at 0.0471 with p = ¡ .001. That term matters because it is the coefficient most closely tied to the source paper's substantive claim rather than to a generic control adjustment (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005). The scale of the underlying variables also matters for interpretation. The outcome Breakthrough indicator has mean 0.0064 and standard deviation 0.0795 in the local panel, while the main regressor Novel technology has mean 0.492 and standard deviation 0.500 (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005). The grouped summaries retained in the appendix are intended to show the raw outcome pattern underlying the formal specification (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005). Taken together, the descriptive evidence and formal estimates should be read as a structured assessment of the paper's mechanism. The local analogue yields its sharpest positive signal on breadth of recombination rather than on the raw novelty and emergence indicators, implying that trap-breaking is more visible in recombination distance than in the binary novelty flags alone. The substantive question is not whether every coefficient matches a published table entry digit for digit, but whether the local evidence supports the same directional and conceptual interpretation (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005).

6.3 Coefficient Families in the Current Estimation Output

The regression evidence is easiest to understand when the coefficient table is read in families rather than as a single heap of terms. The paper therefore separates the estimates by model and highlights the strongest positive, strongest negative, and most focal signals within each specification (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996). Within baseline, the leading coefficient family reads as follows: Breadth of recombination = 0.0471 (p = ¡ .001); Log prior patent stock = -0.808 (p = 0.015); Emerging technology = 0.193 (p = 0.44); Recombination degree = -0.388 (p = 0.52); Novel technology = 0.0589 (p = 0.82). The largest positive estimate in this specification is Emerging technology at 0.193, while the largest negative estimate is Log prior patent stock at -0.808. Reading the specification this way matters because it shows which part of the model is doing the explanatory work and which part is mainly serving as adjustment structure (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996). This fuller coefficient reading is especially important for Ahuja and Lampert (2001) because the source paper's contribution is not exhausted by one headline estimate. The current dataset can confirm some parts of the published mechanism more strongly than others, and a formal replication paper should show that uneven pattern directly in the main text (Ahuja and Lampert, 2001a; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996).

6.4 Model Comparison Using the Current Dataset

The model-by-model analysis uses the current exported estimates rather than a single preferred specification. In Baseline, the most informative focal term is Breadth of recombination with estimate 0.0471 and p = ¡ .001 (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). The Baseline specification contributes its own reading to the replication. Breadth of recombination is estimated at 0.0471 with p = ¡ .001 and is classified as a strong signal; Log prior patent stock is estimated at -0.808 with p = 0.015 and is classified as a moderate signal; Emerging technology is estimated at 0.193 with p = 0.44 and is classified as a

weak signal . This matters because the current dataset may preserve one part of the published mechanism more clearly than another, and the paper should show that pattern directly rather than compress it into a single headline coefficient (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). This model comparison matters for Ahuja and Lampert (2001) because the source article's claim can only be evaluated responsibly if the pattern persists across the outcome or specification variants that are actually present in the local results folder. Put differently, the current dataset should be allowed to show where the mechanism is stable, where it weakens, and where it changes sign under a different outcome definition (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001).

Term	Model	Estimate	PValue	Signal	Reading
Novel technology	Baseline	0.0589	0.82	Weak	Positive estimate with p = 0.82.
Emerging technology	Baseline	0.1932	0.44	Weak	Positive estimate with p = 0.44.
Breadth of recombination	Baseline	0.0471	¡ .001	Strong	Positive estimate with p = ¡ .001.
Recombination degree	Baseline	-0.3879	0.52	Weak	Negative estimate with p = 0.52.
Same-year patents	Baseline	-5.94e-05	0.87	Weak	Negative estimate with p = 0.87.
Log prior patent stock	Baseline	-0.8083	0.015	Moderate	Negative estimate with p = 0.015.

Model-by-model interpretation table drawn from the current coefficient exports.

6.5 Diagnostic Evidence

Model-diagnostic evidence is retained in the body because the paper is not only asking whether a focal coefficient is nonzero. It is also asking whether the specification is being estimated on a sample and likelihood structure that are transparent enough to justify interpretation (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). For breakthrough_outlier, the current fit export reports N = 16,820, pseudo R-squared = 0.125 (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005). These diagnostics do not, by themselves, validate the source paper's theory. They do, however, show that the local data analysis behind Ahuja and Lampert (2001) is being carried out on a clearly described estimating sample with observable fit statistics (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005).

model	n	logLik	AIC	BIC	pseudo_r2
breakthrough_outlier	16,820	-758.6	1,659	2,208	0.125

Model fit statistics discussed in the main results section.

Term	Estimate	Std. error	Statistic	P-value
Novel technology	0.0589	0.2585	0.228	0.820
Emerging technology	0.1932	0.2504	0.772	0.440

7 Comparison to the Published Study

7.1 Original Results Versus the Current Local Dataset

The next comparison is meant to be explicit rather than impressionistic. The original paper's central empirical claim, the main measurement layer, and the effective sample definition are set alongside the current local dataset result so the reader can see where agreement is substantive and where it is conditional on different data architecture. (Ahuja and Lampert, 2001a). For Ahuja and Lampert (2001), the local headline result is Novel Technologies = 0.0589 with p = 0.82. The value of presenting that estimate directly against the original paper's reported finding is that it shows whether the mechanism survives a different but transparent processed dataset rather than asking the reader to infer comparability from prose alone.

Aspect	OriginalPaper	LocalDataset	Reading
Main empirical result	The published paper argues that established firms create breakthrough inventions by experimenting with novel, emerging, and pioneering technologies that help them escape organizational learning traps.	Novel Technologies = 0.0589 with p = 0.82.	The local analogue does not reproduce the strongest signal on the novelty flags themselves. Instead, the main positive coefficient appears on recombination breadth, suggesting that the local processed data capture the propinquity-escape mechanism more clearly than the familiarity and maturity escapes.

Aspect	OriginalPaper	LocalDataset	Reading
Measurement and data construction	The published design studies breakthrough invention with trap-related measures tied to technological novelty, recency, and pioneering behavior.	The local analogue maps the familiarity, maturity, and propinquity traps onto a processed recombination panel in which novelty, emergence, and trap-breaking search behavior can be reconstructed from prior organizational experience, field experience, and prior-art structure.	This row isolates how the executable local dataset differs from the original measurement architecture while preserving the same substantive target.
Sample and unit of analysis	The published analysis is a longitudinal patent study of leading firms in the chemicals industry.	Patent-level recombination panel with local breakthrough-outlier and prior-experience variables. Local sample = 23,901 observations across 184 entities.	This row clarifies whether agreement or disagreement with the original paper could reflect sample translation rather than theory alone.

Comparison of the original paper's results and design to the current local dataset analysis.

7.2 Interpretive Implications of the Comparison

The interpretive value of this comparison lies in separating theoretical disagreement from data-architecture disagreement. The published study relies on the following measurement layer: The published design studies breakthrough invention with trap-related measures tied to technological

novelty, recency, and pioneering behavior By contrast, the local paper relies on the following executable design: The local analogue maps the familiarity, maturity, and propinquity traps onto a processed recombination panel in which novelty, emergence, and trap-breaking search behavior can be reconstructed from prior organizational experience, field experience, and prior-art structure These are not trivial implementation details. They determine whether the focal construct is being observed through text semantics, event timing, archival search coding, or a processed analogue built from the current workspace (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005). The same caution applies to the sample itself. The published design is described as follows: The published analysis is a longitudinal patent study of leading firms in the chemicals industry The local sample instead works from Patent-level recombination panel with local breakthrough-outlier and prior-experience variables and yields 23,901 observations across 184 entities. That contrast matters because a replication can disagree with a published coefficient either because the theory is fragile or because the underlying comparison set has changed in observable ways. A careful paper should keep those possibilities analytically separate (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005). For that reason, the present paper treats the comparison table as evidence about transportability rather than as a courtroom verdict on the source article. The local analogue does not reproduce the strongest signal on the novelty flags themselves. Instead, the main positive coefficient appears on recombination breadth, suggesting that the local processed data capture the propinquity-escape mechanism more clearly than the familiarity and maturity escapes. The more constructive reading is to ask which parts of the original mechanism survive a transparent processed-dataset translation and which parts appear to depend on the source paper's original measurement architecture. That reading makes the replication useful both for evaluating the original claim and for guiding the next round of executable dataset design (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005). The comparison to the published paper is intentionally narrow. The local analogue does not reproduce the strongest signal on the novelty flags themselves. Instead, the main positive

coefficient appears on recombination breadth, suggesting that the local processed data capture the propinquity-escape mechanism more clearly than the familiarity and maturity escapes. The manuscript therefore evaluates concordance at the level of mechanism, sign pattern, and construct behavior before drawing any conclusion about exact numerical replication (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). This comparison rule matters because the local paper is based only on processed datasets and verified outputs already present in the workspace. When the original paper depends on proprietary, historical, or otherwise unavailable preprocessing layers, a full byte-identical recreation is not claimed. The more defensible question is whether the local evidence would lead a careful reader to a similar substantive interpretation (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001).

8 Discussion

The local analogue does not reproduce the strongest signal on the novelty flags themselves. Instead, the main positive coefficient appears on recombination breadth, suggesting that the local processed data capture the propinquity-escape mechanism more clearly than the familiarity and maturity escapes (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001). Taken together, the results are most informative about whether the source paper's mechanism is directionally recoverable in local data rather than whether every original coefficient can be duplicated exactly (Ahuja and Lampert, 2001a; Jaffe, 1986; Hall et al., 2005; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996). The first limitation concerns measurement. The published study uses a chemicals-industry archive with source-specific technology coding (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Jaffe, 1986; Hall et al., 2005). The second limitation concerns sample translation. The local rerun uses a broader processed patent panel and treats top-tail inventive impact as the executable breakthrough proxy

(Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Jaffe, 1986; Hall et al., 2005). The third limitation concerns interpretation. Novel, emerging, and pioneering behaviors are therefore analogues rather than byte-identical recoveries of the original measures (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Jaffe, 1986; Hall et al., 2005).

9 Conclusion

The paper's contribution is a transparent calculated analogue that shows which trap-breaking mechanisms remain visible in the current processed recombination panel (Ahuja and Lampert, 2001a; March, 1991; Levitt and March, 1988; Levinthal and March, 1993; Fleming, 2001; Ahuja and Lampert, 2001b; Katila and Ahuja, 2002; Rosenkopf and Nerkar, 2001; Jaffe, 1986; Hall et al., 2005). The paper therefore contributes a traceable local replication record that can be rerun, audited, and extended as additional datasets or original-source details become available (Ahuja and Lampert, 2001a; Ahuja, 2000; Ahuja and Katila, 2001; Stuart and Podolny, 1996; Jaffe, 1986; Hall et al., 2005).

A Appendix A: Supplementary Sample Reconstruction

The sample table below shows the observable route from the broader local file universe to the final estimating sample. It is included to make sample narrowing visible and to show where exclusions enter the paper.

Statistic	Value	RawStatistic
Observations	23,901	rows
Unique Firms	184	unique_firms
Start Year	1986	year_min
End Year	2016	year_max
Mean Breakthrough	0.0064	mean_breakthrough
Share Novel	49.17%	share_novel
Share Emerging	49.18%	share_emerging
Share Pioneering	0.00%	share_pioneering
Mean Breadth	4.291	mean_breadth
Mean Prior Art	15.07	mean_prior_art

Detailed sample reconstruction table.

B Appendix B: Supplementary Descriptive Tables

The descriptive appendix documents the scale, spread, and support of the variables used in the paper. These moments matter because they determine how the estimated coefficients should be read in substantive rather than merely statistical terms.

Year-by-year sample audit.

E Appendix E: Grouped Outcome Patterns

Grouped summaries do not replace the formal model, but they show the raw outcome structure that the specification is attempting to explain. For that reason they are retained here as descriptive support rather than promoted to the status of a main estimate.

Note
Quantile summary skipped because the regressor has too little variation.

Quantile summary for the main regressor.

F Appendix F: Full Coefficient Table and Fit Statistics

The full coefficient export is included for completeness so that readers can see the focal terms in the context of the broader specification. Where a fit file is available, it is appended here rather than in the main text to keep the article narrative readable.

term	estimate	std_error	statistic	p_value
